

Macroeconomic Theory 102  
Winter 2015 - François Geerolf  
Midterm 1  
Wednesday, January 28, 2015  
Time Limit: 75 Minutes

Last Name: \_\_\_\_\_

First Name: \_\_\_\_\_

Teaching Assistant: \_\_\_\_\_

Student ID Number: \_\_\_\_\_

Signature \_\_\_\_\_

---

## Test A

This exam contains 9 pages (including this cover page). You can earn 100 points + 6 bonus points. If you are stuck at some point, don't forget to answer the easy questions worth many points ! (there are many of them)

### Instructions:

1. Print your Last name, First Name, Teaching Assistant Name (as a reminder, teaching assistants are: Flavien Moreau, Keyyong Park, Matias Vieyra, and Gabriel Zaourak), Student ID Number and Signature at the top of this page.
2. The only items which should be on your desk are pencils and/or pens. NO other items are allowed. Place any other item UNDER your desk. Calculators are NOT allowed.
3. Once the exam begins, you are not allowed to leave the room until you hand in your exam.

**Good luck ! Budget your time wisely ! (skip the question or even the exercise if you get stuck)**

Grade Table (FOR TEACHER USE ONLY)

Question	Points	Score
1	10	
2	14	
3	6	
4	20	
5	20	
6	36	
Total:	106

## Multiple Choice (10 points)

1. (10 points) These are **multiple choice** questions. Mark box if true.
  - (a) (2 points) If per capita GDP in 2013 was \$20000, and per capita GDP in 2015 is \$20200, then how much approximately was the growth rate of per capita GDP every year?
    - 1%
    - 10%
    - 0.5%
  - (b) (2 points) Over the past 50 years, Brazil's population growth rate has averaged about 2.3 percent. According to the rule of 70, Brazil's population will double in about:
    - 3 years.
    - 30 years.
    - 33 years.
    - 161 years.
    - 1.6 years.
  - (c) (2 points) The key difference between the Solow model and the production model is:
    - The Solow model endogenizes the process of capital accumulation.
    - The standard model endogenizes the process of capital accumulation.
    - The Solow model uses different values for the capital share.
    - The Solow model does not contain a productivity measure.
    - The Solow model exogenizes the process of capital accumulation.
  - (d) (2 points) In the Solow model, if we assume that capital depreciation rates are the same across all countries, differences in per capita output can be explained by:
    - the steady state capital stock.
    - the initial capital stock and saving rates.
    - differences in productivity and saving rates.
    - the labor stock and saving rates.
    - None of these answers are correct.
  - (e) (2 points) An implication of the Solow model is that once an economy reaches the steady state:
    - per capita consumption is constant.
    - per capita output is constant, but per capita capital is not
    - per capita capital is variable
    - per capita consumption continues to grow
    - per capita consumption is growing.

## Two Questions directly from the course (20 points)

2. (14 points) Assume that production is given by the following production function:  $Y_t = A_t K_t^a L_t^b$ , and that  $A_t = \bar{A}$ . Give **short answers**, you won't be penalized if you do not write sentences. Go quickly to the next sections.

(a) (2 points) What is the name of this production function?

.....

(b) (2 points) What is the relationship between  $a$  and  $b$  in this production function, if returns to scale are constant? (with respect to capital and labor)

.....

(c) (2 points) Why do macroeconomists use this production function, a power function of the quantity of capital and the quantity of labor? What statistical regularity makes them confident to use this function?

.....  
 .....

(d) (2 points) What are  $a$  and  $b$  equal to typically?

.....

(e) (2 points) Why are they equal to these numbers?

.....

(f) (2 points) Write an example of a production function with the same inputs (technology  $A_t$ , capital  $K_t$  and labor  $L_t$ ), but decreasing returns to scale. (with respect to capital and labor)

.....

(g) (2 points) Write an example of a production function with the same inputs, but increasing returns to scale. (again, with respect to capital and labor)

.....

3. (6 points) Quantity indexes.

(a) (3 points) Define the Laspeyres index and the Paasche index.

.....  
 .....

(b) (3 points) What is the Fischer (or chain-weighted) index?

.....  
 .....  
 .....

## Exercise 1 (20 points)

4. (20 points) Consider the following model of the labor market, with labor supply  $L^s$  and labor demand  $L^d$  respectively given as a function of the wage by:

$$L^s = \bar{a}w + \bar{l}$$

$$L^d = \bar{f} - w.$$

- (a) (2 points) In the following box, represent this model graphically, as well as its equilibrium  $(L^*, w^*)$ . Represent an increase in  $\bar{a}$  on the graph, using a dotted line. Represent the effect of this increase in  $\bar{a}$  on the wage and the effect on employment.

- (b) (2 points) Again, represent the labor market model in the following box, but this time consider a decrease in  $\bar{f}$ . Represent the effect on the wage and the effect on employment.

- (c) (4 points) One last time, represent the labor market model in the following box, but consider the introduction of a proportional tax  $\tau$  on wages such that when  $w$  is paid by employers, employees actually only receive  $w(1 - \tau)$ . Show the triangle corresponding to deadweight loss (also known as Harberger's (1924-) triangle).

(d) (4 points) Solve analytically for the equilibrium values of  $L^*$  and  $w^*$  in this model with no taxes.

.....  
.....  
.....  
.....  
.....  
.....

(e) (4 points) Show analytically the effect on the  $L^*$  and  $w^*$  of the two previous experiments (increase in  $\bar{a}$ , decrease in  $\bar{f}$ ).

.....  
.....  
.....  
.....

(f) (4 points) Show analytically the effect on the equilibrium wage  $w^*$  and employment  $L^*$  of the tax  $\tau$ , as a function of  $\tau$ .

.....  
.....  
.....  
.....  
.....  
.....

### Exercise 3 (30 points + 6 bonus points)

6. (36 points) We consider an economy with the following production function:  $Y_t = \bar{A}K_t^{1/3}L_t^{2/3}N_t$ , where the amount of land  $N_t$  is also entering as an input in the production function. (firms need land to produce, for example because they need offices) Assume that the number of people working is fixed and given by:  $\bar{L}$ . Capital depreciates at rate  $\bar{d}$ , and the savings rate is constant equal to  $\bar{s}$ . It is also assumed that there is a fixed quantity of land in the economy given by  $\bar{N}$ .

(a) (6 points) Write the law of motion for capital, as a function of  $Y_t$  and  $K_t$ .

.....

(b) (6 points) Replace  $Y_t$  in the previous expression, to derive the law of motion for the capital stock, where only the capital stock and exogenous variables appear.

.....  
 .....  
 .....  
 .....  
 .....

(c) (6 points) Explain, using a graph as well as words why the level of capital converges to a steady-state. Take the example of an initially lower than steady state amount of capital  $K_0 < K^*$ . (*Hint:* note that the introduction of land does not fundamentally change the capital accumulation process, as land is assumed to be in constant supply.)

.....  
.....  
.....  
.....  
.....  
.....  
.....

(d) (6 points) What is the marginal product of land?

.....  
.....  
.....  
.....

(e) (6 points) Imagine the economy starts with an initially too low level of capital (relative to the steady state level). How does the marginal product of land varies over time? Why?

.....  
.....  
.....  
.....  
.....  
.....

(f) (6 points) **Bonus:** extend this model to one where there is a research sector, a production sector, and ideas accumulate over time. Go as far as you can in that investigation. (if needed, use the back of the sheet !)

.....  
.....  
.....  
.....  
.....  
.....
